

# Search for the Flavor Changing Neutral Current, $t \rightarrow q\gamma$ , in Top Pair Events Using the ATLAS Detector

Jason Barkeloo

April 16, 2020

# Welcome!

Thank you for your flexibility given our current situation!

Defense proceedings:

- ▶ Open/public presentation in this room with followup questions
- ▶ Committee and myself will adjourn to a separate room to conclude
- ▶ Committee will deliberate and I will return to this room

General Guidelines:

- ▶ Please mute if not speaking

**Thank you for attending!**

# Overview

Background

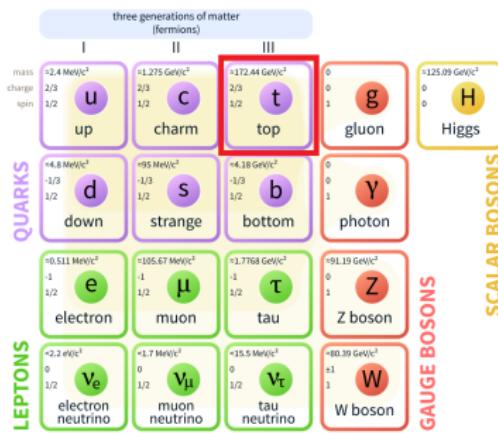

The LHC and ATLAS

Searching for Flavor Changing Neutral Current Signatures

Conclusion

# The Standard Model

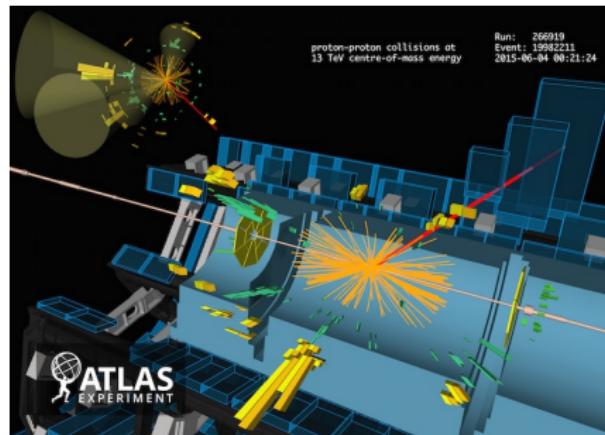

## Standard Model of Elementary Particles

- ▶ Best working description of fundamental particles and their interactions
    - ▶ Experimentally precise and well behaved

# The Top Quark

- ▶ Heaviest fundamental particle, 172.5 GeV
- ▶ Lifetime  $5 \times 10^{-25}$  s, decays before hadronization
  - ▶ Allows us to study the decay of a single quark

# Top Quark Pair Production

- ▶ Leading order processes for top quark production
  - ▶ Quark-antiquark annihilation  $\approx 10\%$
  - ▶ Gluon-gluon fusion  $\approx 90\%$

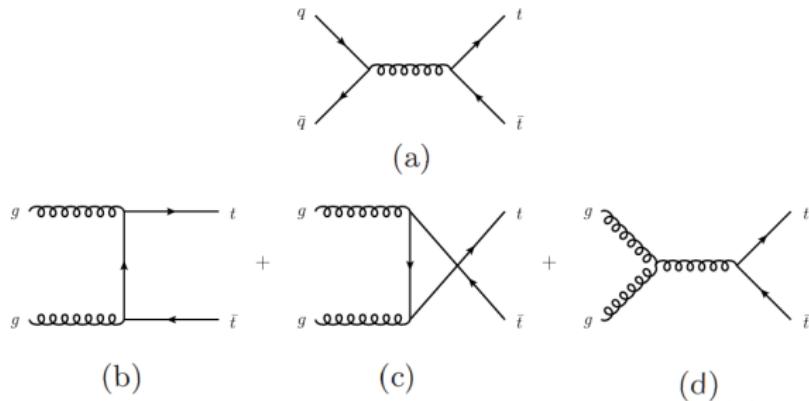

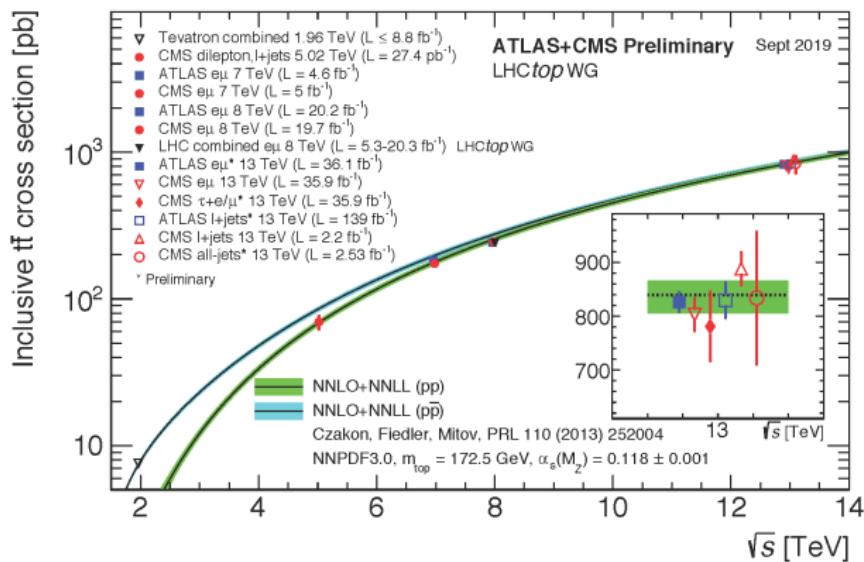

Figure: Leading order  $t\bar{t}$  diagrams

# Top Quark Pair Production

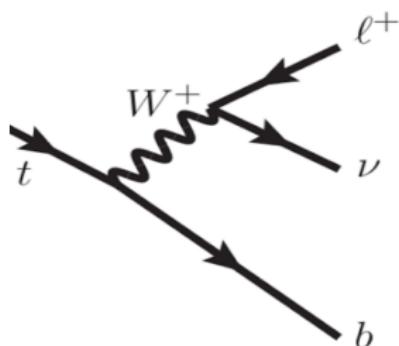

- At  $\sqrt{s} = 13 \text{ TeV}$  for  $m_t = 172.5 \text{ GeV}$ ,  $\sigma_{t\bar{t}} = 831.76 \text{ pb}$

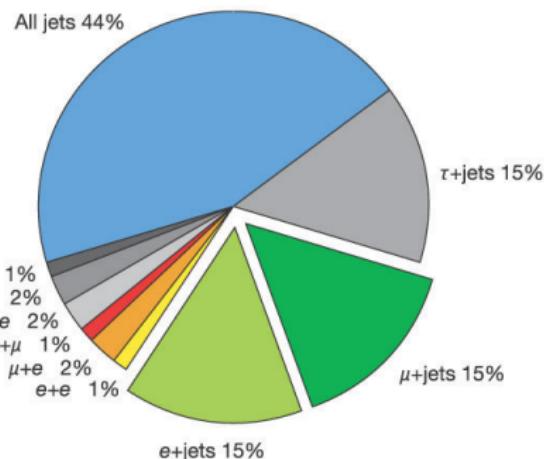

**Figure:**  $t\bar{t}$  production cross section [TopWGSummaryPlots]

# Top Quark Decays

- ▶ Standard model top branching ratio to  $bW \simeq 100\%$

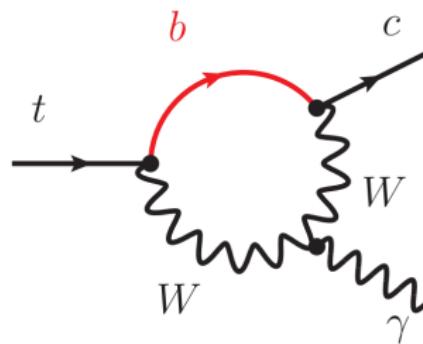

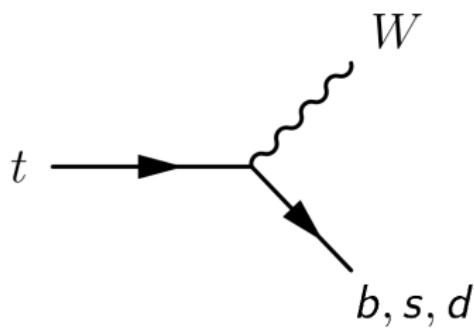

**Figure:** Leptonic final state diagram for a top decay

**Figure:** Top quark pair decay final states [Nature]

## Top Quark Decays in the SM

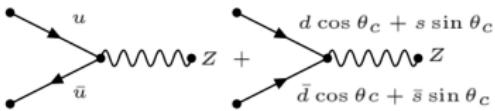

- ▶  $t \rightarrow bW \approx 99.83\%$
- ▶  $t \rightarrow sW \approx 0.16\%$
- ▶  $t \rightarrow dW \approx 0.01\%$

- ▶  $t \rightarrow q_{u,c}X \approx 10^{-17} - 10^{-12}$
- ▶ Limits on  $t \rightarrow \gamma q$  processes:  
[Phys.Lett. B800 135082]
  - ▶  $t \rightarrow \gamma u < 2.8 \times 10^{-5}$
  - ▶  $t \rightarrow \gamma c < 18 \times 10^{-5}$

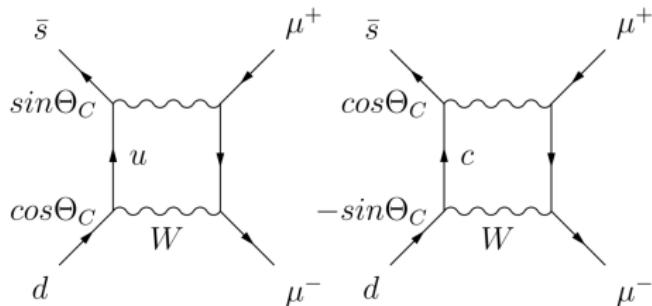

# GIM Mechanism

- ▶ Cabibbo model - 3 quarks ( $u, d, s$ )
- ▶ Studies of kaon decays showed the existence of  $K^+ \rightarrow \mu^+ \nu_\mu$  but an absence of predicted  $K_L^0 \rightarrow \mu^+ \mu^-$
- ▶ Even in the absence of a tree level decay  $K_L^0$  decay the box diagram would be possible through an exchange of W bosons
- ▶ Weak neutral current interactions in the uds model have the form

$$u\bar{u} + (d\bar{d} \cos^2 \theta_C + s\bar{s} \sin^2 \theta_C) + (s\bar{d} + d\bar{s}) \sin \theta_C \cos \theta_C$$

# GIM Mechanism

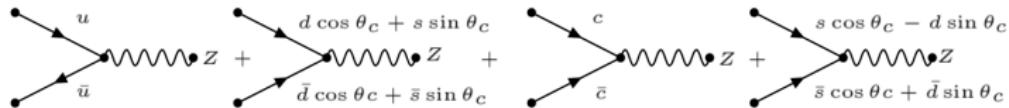

- ▶ Glashow, Iliopoulos, and Maiani [Phys. Rev. D (1970)] propose a mechanism through which FCNCs are suppressed in loop diagrams
  - ▶ Introduction of charm quark
- ▶ Kaon decays imply no neutral current/natural suppression of neutral current

# GIM Mechanism

$$\begin{bmatrix} d' \\ s' \end{bmatrix} = \begin{bmatrix} \cos \theta_c & \sin \theta_c \\ -\sin \theta_c & \cos \theta_c \end{bmatrix} \begin{bmatrix} d \\ s \end{bmatrix}$$

- ▶ The addition of the charm changes our weak neutral current interactions
  - ▶ With four quarks the weak neutral interactions now have the form:
- $$u\bar{u} + c\bar{c} + (d\bar{d} + s\bar{s}) \cos^2 \theta_C + (s\bar{s} + d\bar{d}) \sin^2 \theta_C + (s\bar{d} + d\bar{s} - d\bar{s} - s\bar{d}) \sin \theta_C \cos \theta_C$$
- ▶ Flavor changing neutral current diagrams cancel out at tree level (as  $m_c \rightarrow m_u$ )

# CKM Matrix

$$\begin{bmatrix} |V_{ud}| & |V_{us}| & |V_{ub}| \\ |V_{cd}| & |V_{cs}| & |V_{cb}| \\ |V_{td}| & |V_{ts}| & |V_{tb}| \end{bmatrix} = \begin{bmatrix} 0.97427 \pm 0.00015 & 0.22534 \pm 0.00065 & 0.00351^{+0.00015}_{-0.00014} \\ 0.22520 \pm 0.00065 & 0.97344 \pm 0.00016 & 0.0412^{+0.0011}_{-0.0005} \\ 0.00867^{+0.00029}_{-0.00031} & 0.0404^{+0.0011}_{-0.0005} & 0.999146^{+0.000021}_{-0.000046} \end{bmatrix}$$

Figure: CKM Matrix

- ▶ Decay rates proportional to  $|V_{tx}|^2$
- ▶ Top decay through a  $W^\pm$  boson is a charged current interaction.
- ▶ Flavor changing processes are proportional to off-diagonal elements of the CKM matrix
- ▶ GIM/CKM suppression of these FCNC processes in the Standard Model make them unlikely to be seen without some new physics

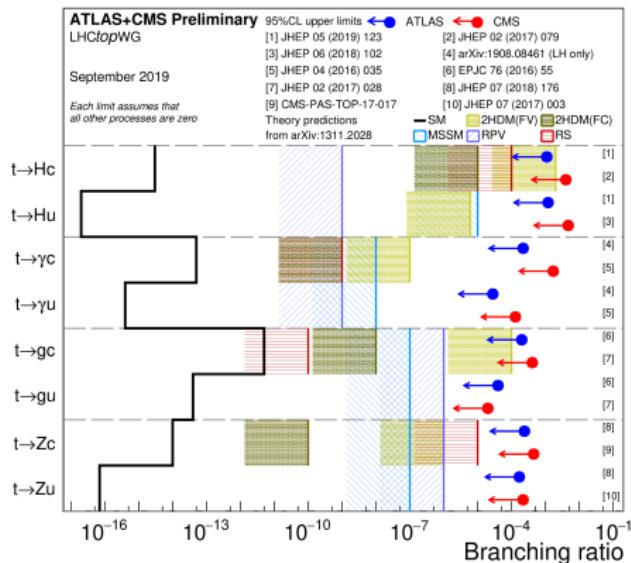

# Top Flavor Changing Neutral Currents (FCNCs)

Process	SM	2HDM(FV)	2HDM(FC)	MSSM	RPV	RS
$t \rightarrow Zu$	$7 \times 10^{-17}$	—	—	$\leq 10^{-7}$	$\leq 10^{-6}$	—
$t \rightarrow Zc$	$1 \times 10^{-14}$	$\leq 10^{-6}$	$\leq 10^{-10}$	$\leq 10^{-7}$	$\leq 10^{-6}$	$\leq 10^{-5}$
$t \rightarrow gu$	$4 \times 10^{-14}$	—	—	$\leq 10^{-7}$	$\leq 10^{-6}$	—

**Table:** Branching ratio enhancements in various beyond the standard model theories [Snowmass Top Report]

## Top Flavor Changing Neutral Currents

### ► Current Limits on FCNC Decays

- ▶ Limits on  $t \rightarrow q\gamma$  processes: [JHEP 04 (2016) 035]
    - ▶  $t \rightarrow \gamma u < 2.8 \times 10^{-5}$
    - ▶  $t \rightarrow \gamma c < 18 \times 10^{-5}$

# Monte Carlo Production of FCNC Signal Samples

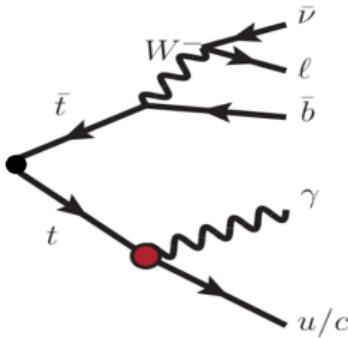

- ▶ Due to the low cross sections we must create our own Monte Carlo Samples for our Signal
- ▶ An effective field theory approach was taken in the creation of the model [Degrande et al. Phys. Rev. D 91, 034024 (2015)]
- ▶ This model takes advantage of dimension-6 operators

$$\mathcal{L}_{SM} = \mathcal{L}_{SM}^{(4)} + \mathcal{L}^{eff} \text{ where } \mathcal{L}^{eff} = \frac{1}{\Lambda^2} \sum_k C_k^{(6)} Q_k^{(6)}$$

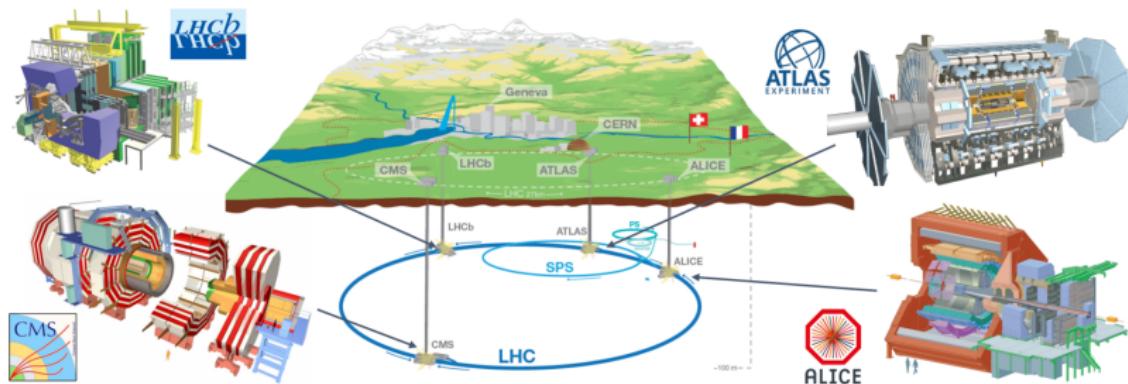

$$\mathcal{L}_{tq\gamma}^{eff} = C \sigma^{\mu\nu} q_\nu (\lambda_{ct}^L P_L + \lambda_{ct}^R P_R) t A_\mu + H.c.$$

# FCNC: What are we looking for? $t\bar{t} \rightarrow W(\rightarrow l\nu)b + q\gamma$

- ▶ Final state topology
  - ▶ One Neutrino, from W
  - ▶ One Lepton, from W
  - ▶ One B-jet, SM Top
  - ▶ One Photon, FCNC Top
  - ▶ One Jet, FCNC Top

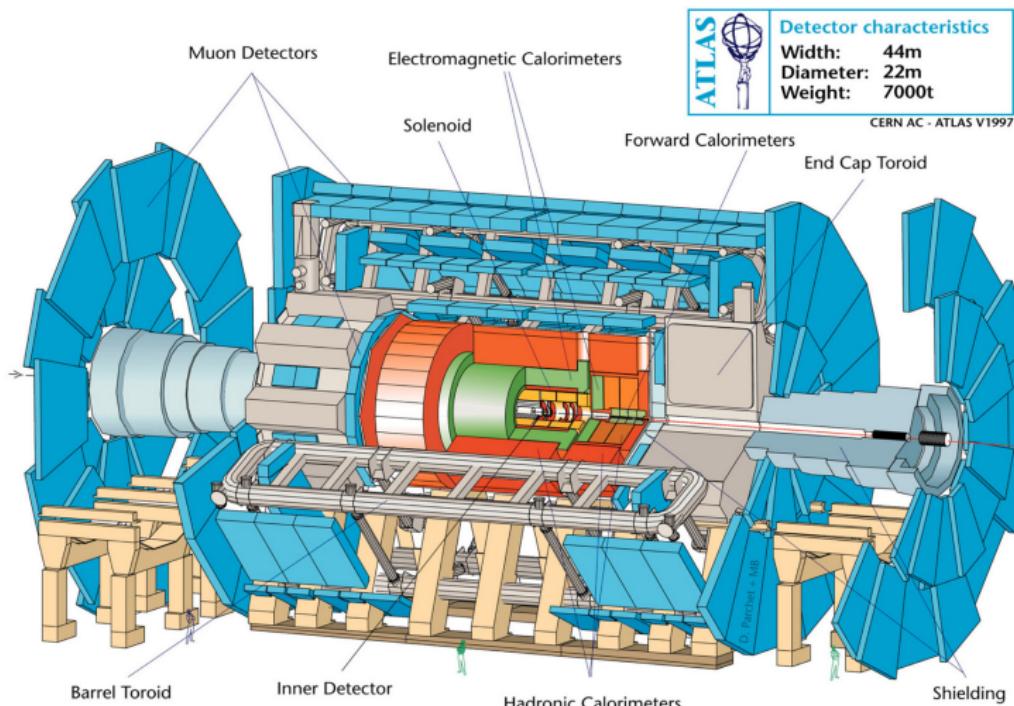

# The Large Hadron Collider

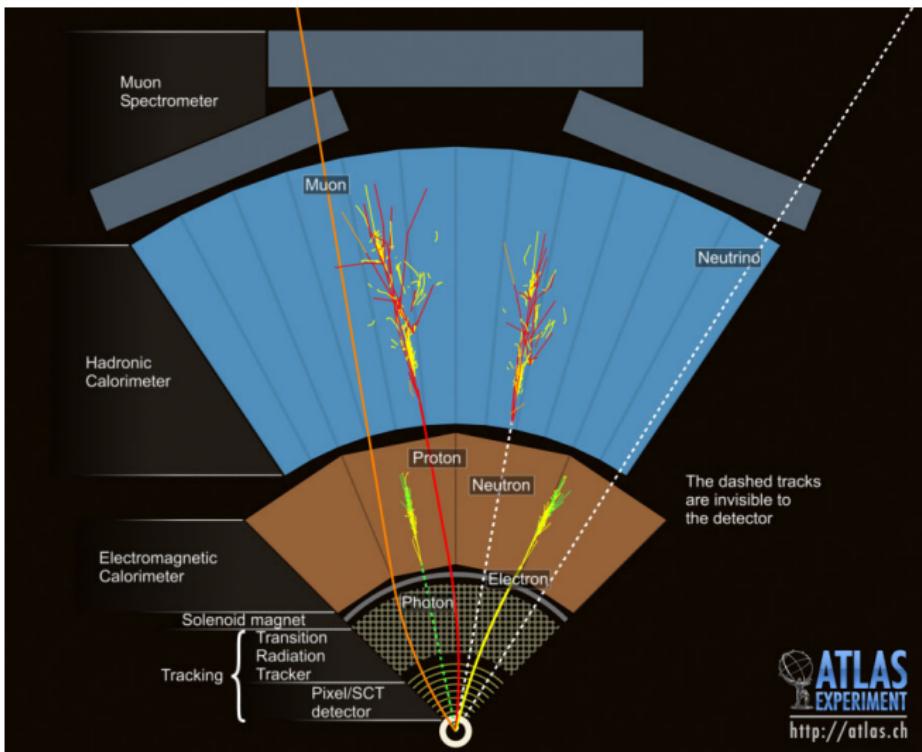

- ▶ 27km ring beneath Franco-Swiss border
- ▶ Collides protons at center of mass energy 13TeV
- ▶ Over 10 Quadrillion ( $10^{15}$ ) events produced within the ATLAS detector so far

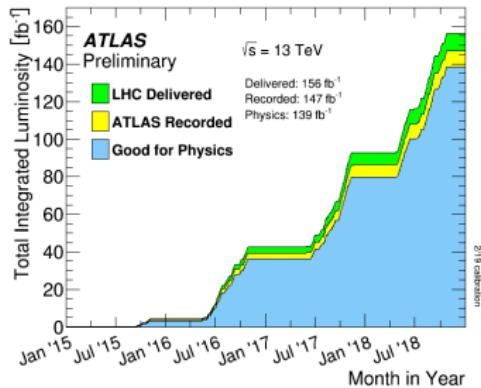

# The ATLAS Detector

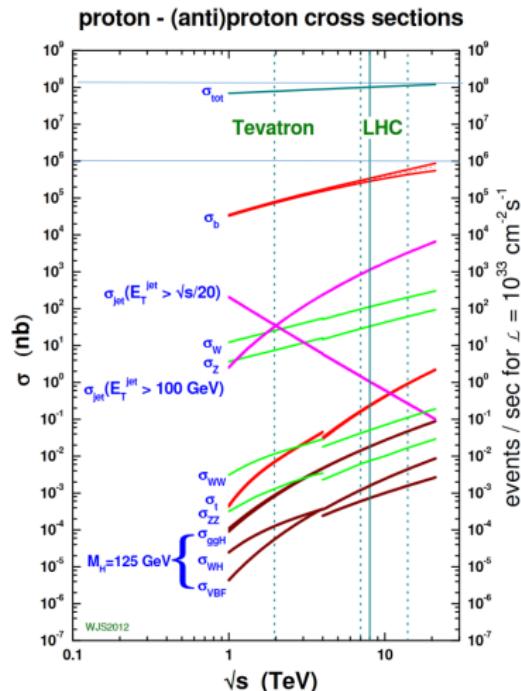

# Particles in ATLAS

# ATLAS Data

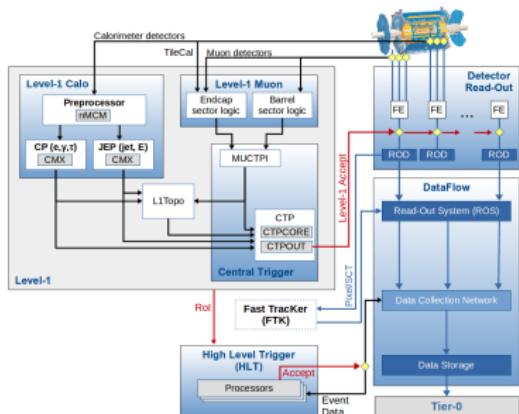

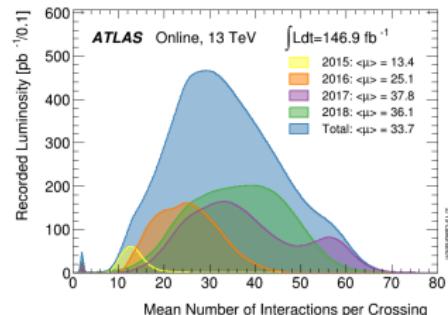

- ▶ Total Luminosity at  $\sqrt{s} = 13$  TeV:  
 $139\text{fb}^{-1}$
- ▶ The number of events we see is  
 $N = \sigma L$
- ▶  $N_{tot} \approx 14 \times 10^{15}$  events produced during the 13TeV data runs
- ▶  $N_{t\bar{t}} \approx 116 \times 10^6$

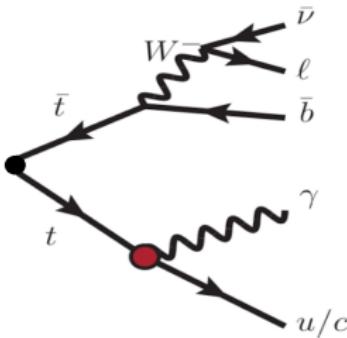

# ATLAS Data Acquisition

- ▶ Average 33.7 collisions per crossing during Run 2, 40MHz collision rate
- ▶ Raw uncompressed event: 1.6 MB
- ▶ Around 64 TB/s data
- ▶ 2 Stage Trigger System
  - ▶ Level 1 - Hardware based, coarse object reconstruction, reduces rate to under 100 kHz
  - ▶ High-Level Trigger: Software based, performs reconstruction as close to offline as possible, reduces rate to 1 kHz
- ▶ Still save 10s of PB per year

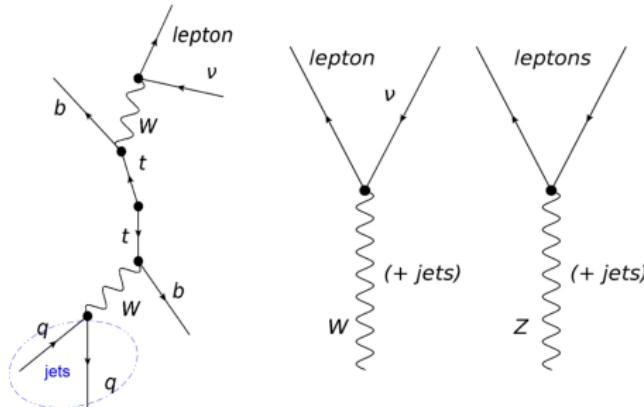

# Signal Region Preselection

- ▶ Preselect events with objects that look like similar to our expected topology
- ▶ Require:
  - ▶ Exactly one lepton ( $e$  or  $\mu$ )  $\geq 25$  GeV
  - ▶ Exactly one good photon  $\geq 50$  GeV
  - ▶ Missing transverse energy  $\geq 30$  GeV
  - ▶  $\geq 2$  jets (at least 1 b-tag)

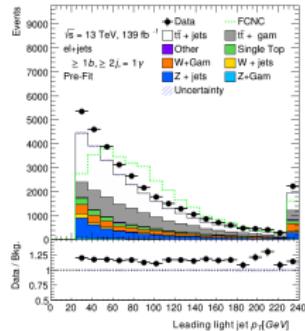

## Background Processes

- ▶ Due to all of the processes at hadron colliders it is important to model similar event topologies well.
- ▶ Major backgrounds include  $t\bar{t}$ , W+Jets, and processes with an associated photon
- ▶ Minor Backgrounds: Z+Jets, Single Top
- ▶ Very Minor Backgrounds: Diboson, tt+V

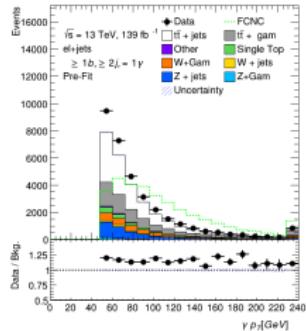

# Preselection Objects

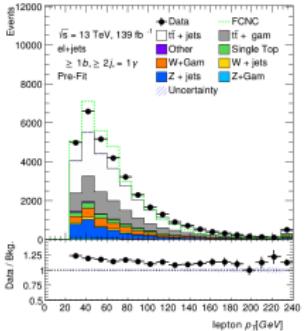

## Electron Channel

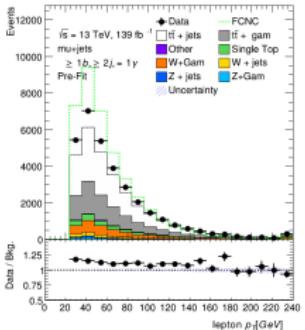

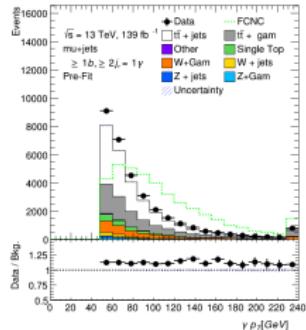

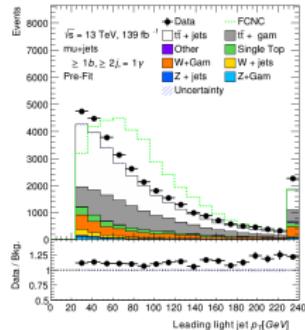

► Photon  $p_T$

► Lepton  $p_T$

## Muon Channel

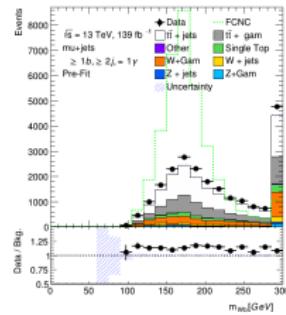

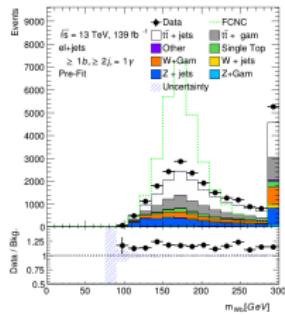

# Top Quarks

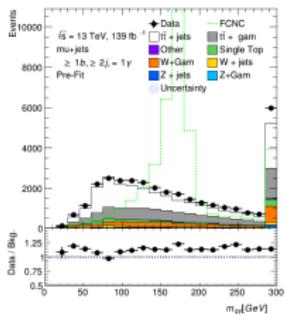

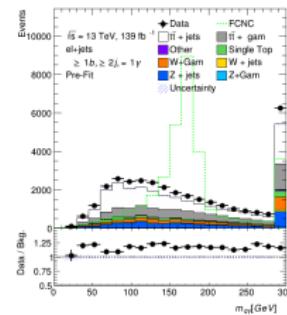

Tops must be reconstructed from these basic physics objects along with b-jets and  $E_T^{\text{miss}}$

- Neutrino z-axis direction is ambiguous, determined by minimization of:  $\chi^2 = \frac{(m_{b,l,\nu} - m_t)^2}{\sigma_{SMtop}^2} + \frac{(m_{l,\nu} - m_W)^2}{\sigma_W^2}$

SM Top:  $m_{Wb}$

FCNC Top:  $m_{q\gamma}$

# Additional Processes

- ▶ QCD Backgrounds are difficult to model at the energies and interaction rates of the LHC
  - ▶ Develop 0 photon regions for scale factors for major backgrounds ( $t\bar{t}$  and W+jets)
- ▶ Photon misidentification i.e., particles being reconstructed as particles ( $e \rightarrow \gamma, j \rightarrow \gamma$ )
  - ▶  $e \rightarrow \gamma$ :  $Z \rightarrow ee$  tag and probe method used for SF calculation
  - ▶  $j \rightarrow \gamma$ : ABCD method used for SF calculation

# 0 Photon Backgrounds

Select events with objects that look like similar to our expected topology for major backgrounds ( $t\bar{t}$ , W+jets) Require:

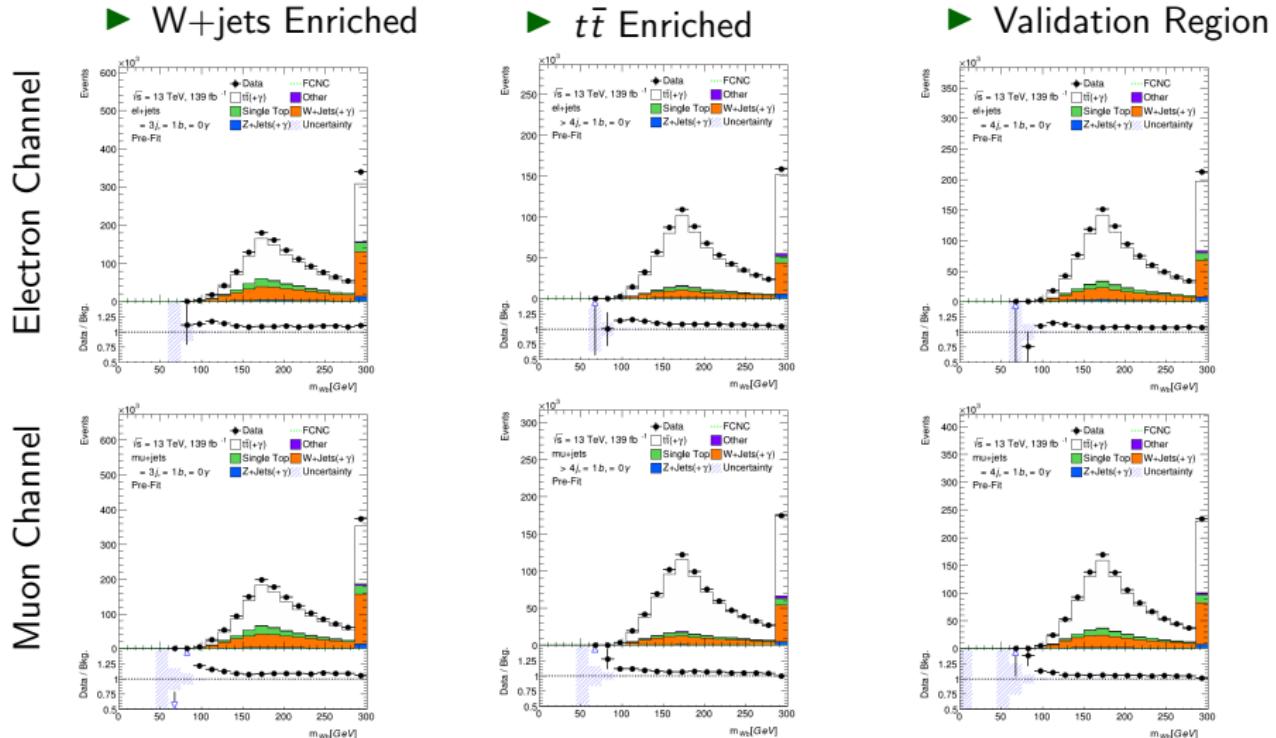

- ▶ Common Object Selection (MET, Triggers, etc.)
- ▶ Exactly one lepton (e or  $\mu$ )  $\geq 25$  GeV
- ▶ Number of Jets to define Regions:
  - ▶ W+jets enriched region:  $n_{\text{jets}} = 3$
  - ▶ Validation Region:  $n_{\text{jets}} = 4$
  - ▶  $t\bar{t}$ +jets enriched region:  $n_{\text{jets}} \geq 5$
- ▶ Exactly 1 b-tagged jet
- ▶  $\geq 2$  jets (at least 1 b-tag)

Calculate scale factors simultaneously:

$$\begin{bmatrix} N(W)_{3j} & N(t\bar{t})_{3j} \\ N(W)_{5+j} & N(t\bar{t})_{5+j} \end{bmatrix} \begin{bmatrix} W_{SF} \\ t\bar{t}_{SF} \end{bmatrix} = \begin{bmatrix} N(\text{data-bkg})_{3j} \\ N(\text{data-bkg})_{5j} \end{bmatrix}$$

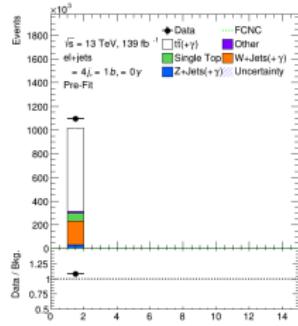

Sample	e+jets SF	$\mu$ +jets SF
W+jets	1.22	1.25
$t\bar{t}$	1.06	1.01

# 0 Photon Scale Factors, $m_{Wb}$ distributions before SF

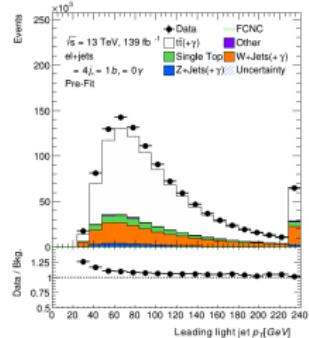

# 0 Photon Regions: VR before/after SF, electron channel

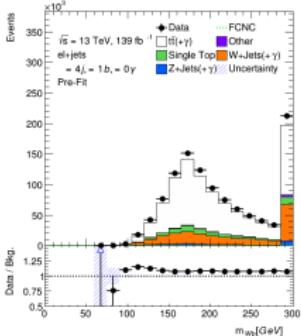

►  $n_{\text{bjets}}$

► Lead Jet  $p_T$

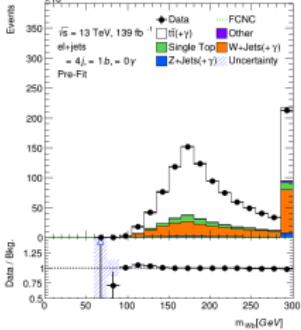

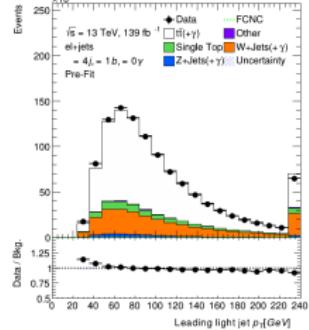

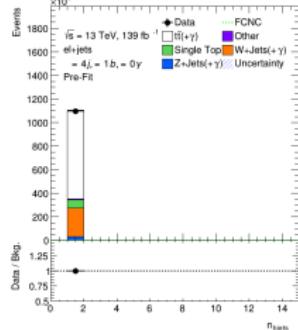

►  $m_{Wb}$

Before SF

After SF

# $e \rightarrow \gamma$ Fake Rate Object Selection

- ▶ Want to calculate fake rate in events which could enter the signal region.
- ▶ Create 2 control regions:  $Z \rightarrow ee$  and  $Z \rightarrow e\gamma$
- ▶ Require:
  - ▶ Common Object Selection (MET, Jets, Triggers, etc.)
  - ▶  $Z \rightarrow ee$  : 2 Opposite Sign Electrons,  $86.1 \text{ GeV} < m_{e^+e^-} < 96.1 \text{ GeV}$
  - ▶  $Z \rightarrow e\gamma$  : 1 Electron,  $\geq 1$  Photon,  $86.1 \text{ GeV} < m_{e\gamma} < 96.1 \text{ GeV}$
- ▶ Tag and Probe Method used

# $e \rightarrow \gamma$ Scale Factor

$$\text{FR}^{\text{e-fake}} = \frac{N_{e,\gamma}}{N_{e,e}}$$

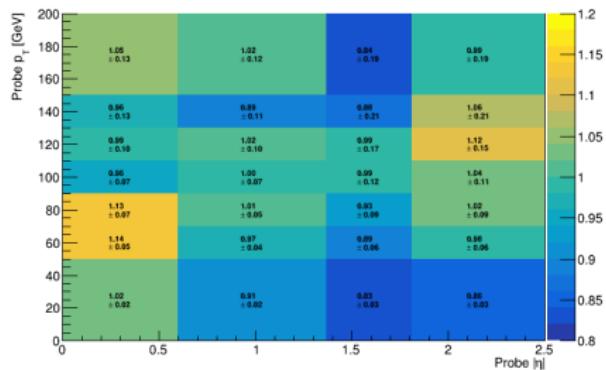

$$\text{SF}_{\text{FR}}^{\text{e-fake}} = \frac{\text{FR}_{\text{data}}^{\text{e-fake}}}{\text{FR}_{\text{MC}}^{\text{e-fake}}}$$

This scale factor is calculated for converted and unconverted photons as well as in bins of  $\eta$  and  $\phi$

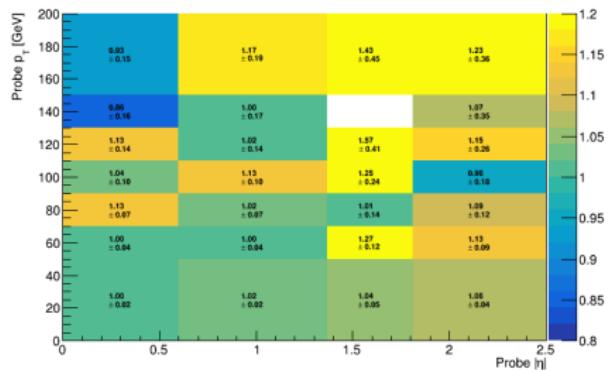

- ▶ Converted photons pair produce before the ECAL leaving tracks in the Inner Detector
- ▶ Unconverted photons only pair produce inside of the ECAL

# $e \rightarrow \gamma$ 2D Fake Rates

## ► Converted $\gamma$

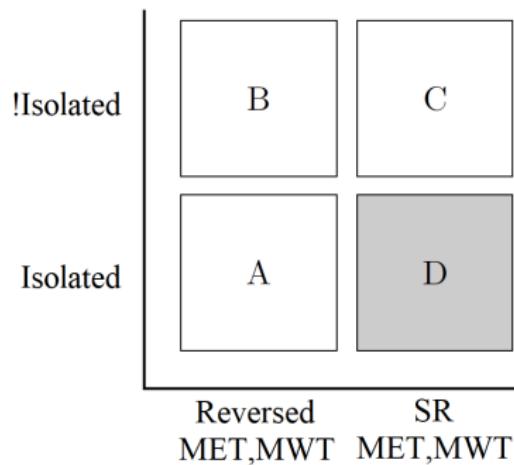

## ► Unconverted $\gamma$

# $j \rightarrow \gamma$ Fake Rates

Majority of hadronic fake photons are from  $t\bar{t}$  events where a final state jet radiates a non-prompt photon. Similarly radiated photons for W+jets and single top processes can enter the signal region through the radiation of a non-prompt photon.

# $j \rightarrow \gamma$ ABCD Method

$$\frac{N_D^{\text{h-fake}}}{N_C^{\text{h-fake}}} = \frac{N_A^{\text{h-fake}}}{N_B^{\text{h-fake}}} \text{ and } \frac{N_D^{\text{h-fake}}}{N_A^{\text{h-fake}}} = \frac{N_C^{\text{h-fake}}}{N_B^{\text{h-fake}}}$$

!Isolated

Isolated

Want uncorrelated variables, use a correction factor to account to ensure closure

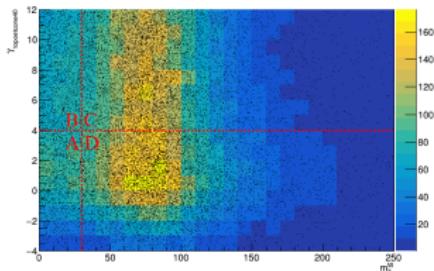

$$\theta_{\text{MC}} = \frac{N_{D,\text{MC}}^{\text{h-fake}} / N_{C,\text{MC}}^{\text{h-fake}}}{N_{A,\text{MC}}^{\text{h-fake}} / N_{B,\text{MC}}^{\text{h-fake}}}$$

$$N_{D,\text{est.}}^{\text{h-fake}} = \frac{N_{A,\text{data}}^{\text{h-fake}} \times N_{C,\text{data}}^{\text{h-fake}}}{N_{B,\text{data}}^{\text{h-fake}}} \times \theta_{\text{MC}}$$

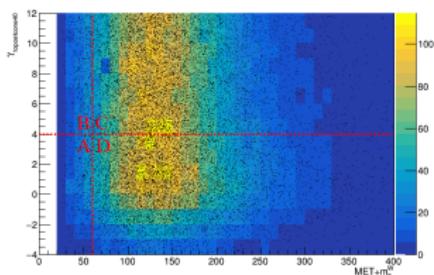

$$\text{SF}^{\text{h-fake}} = \frac{N_{D,\text{est.}}^{\text{h-fake}}}{N_{D,\text{MC}}^{\text{h-fake}}}$$

## ► Converted Photons

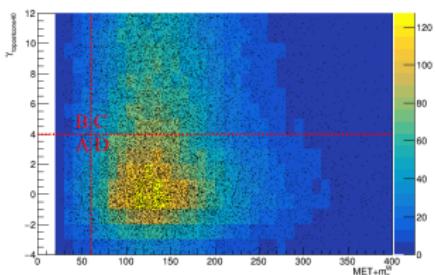

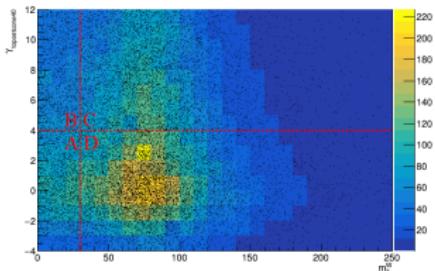

e channel

$\mu$  channel

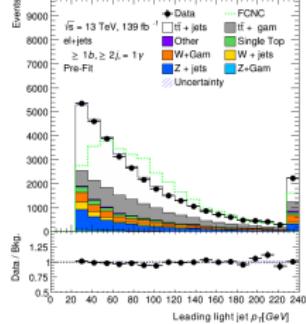

## ► Unconverted Photons

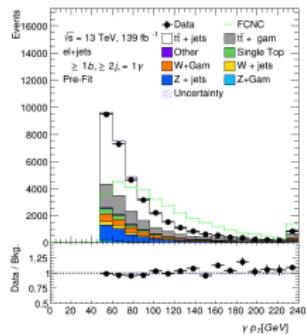

Channel:	Converted	Unconverted
Electron Channel	$1.28 \pm 0.34$	$1.99 \pm 0.52$
Muon Channel	$1.23 \pm 0.50$	$2.27 \pm 0.92$

## Electron Channel

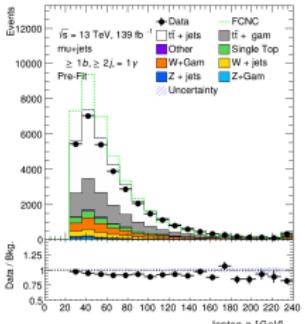

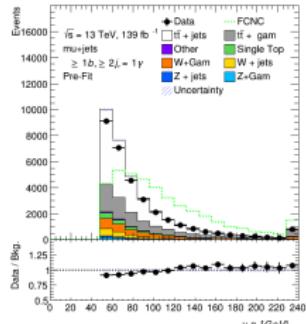

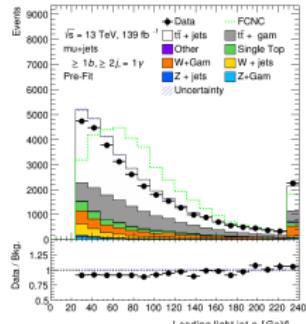

## Photon $p_T$

## Lepton $p_T$

## Muon Channel

# Neural Networks

- ▶ Advanced pattern recognition used to classify events
- ▶ A dense neural network is used with various low and high level variable inputs
- ▶ Supervised learning used to approximate any multidimensional function

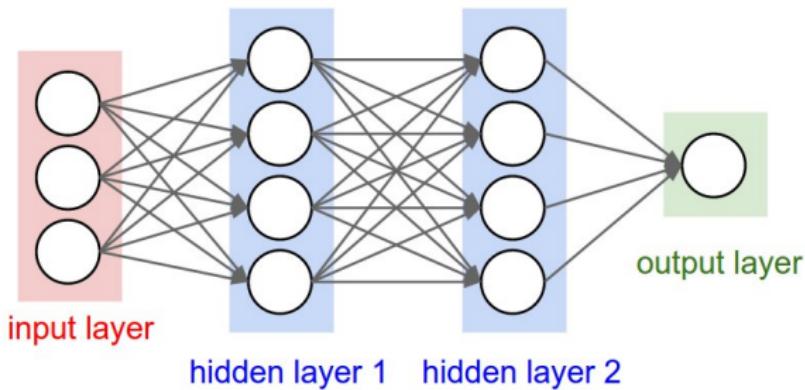

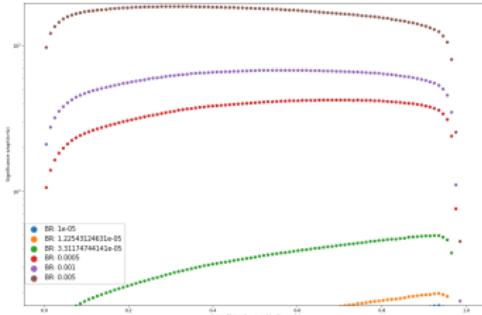

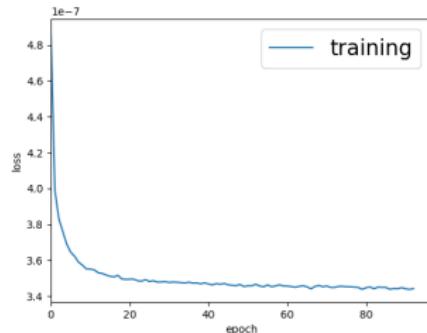

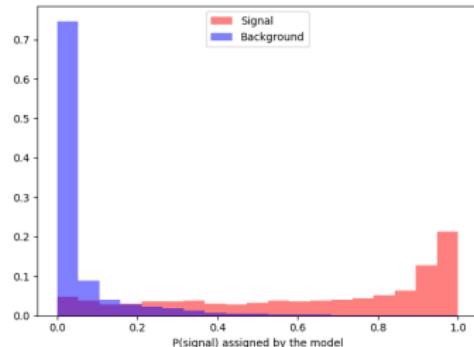

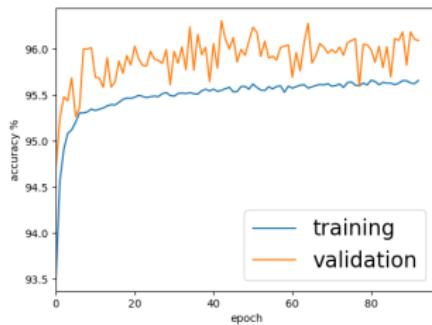

Figure: [Ref: Neural Network]

# Neural Network Model Inputs

- ▶ Using keras on top of tensorflow various network architectures were tested
- ▶ Networks are set up with 1 input layer, 2 hidden layers of 10 nodes, and 1 output node
- ▶ Each hidden layer has 20% dropout to prevent overtraining by removing codependency between nodes
- ▶ Batch size of 100 used and each network is allowed 200 epochs (with patience=50), all models converge and end early with reasonable batch sizes
- ▶ Optimizer: Adam
- ▶ Loss Function: Binary Cross Entropy

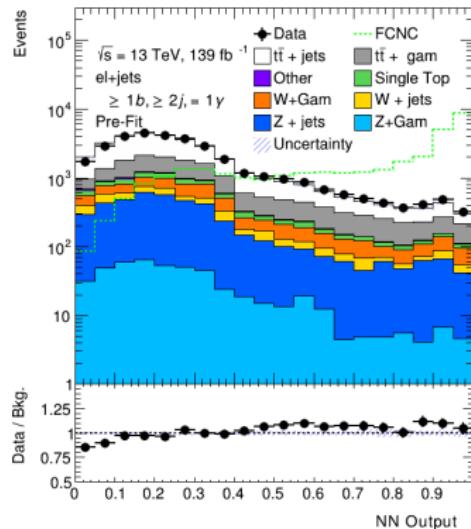

# Neural Network Outputs

## e+jets Channel Example

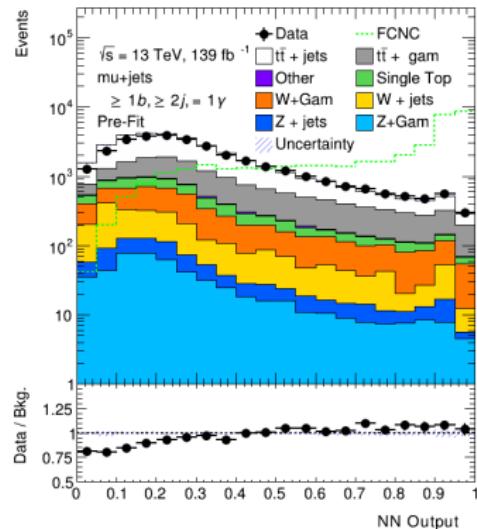

# Scaled Preselection Neural Network Outputs

## Electron Channel

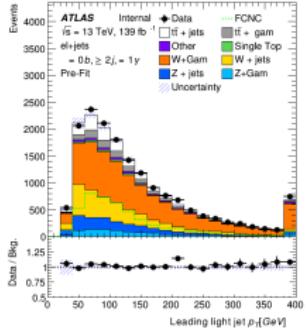

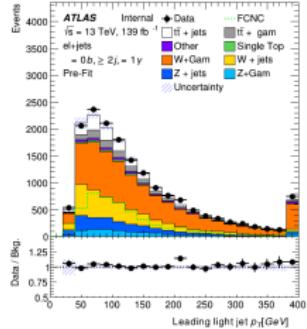

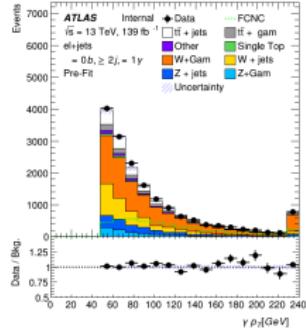

## Muon Channel

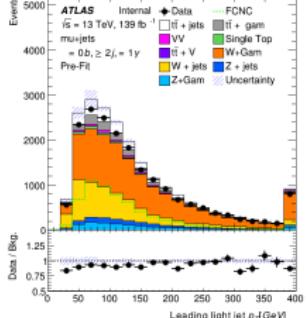

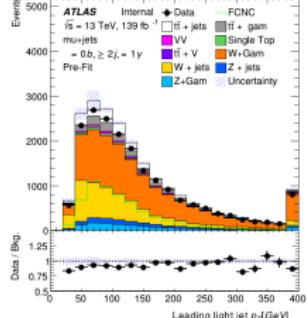

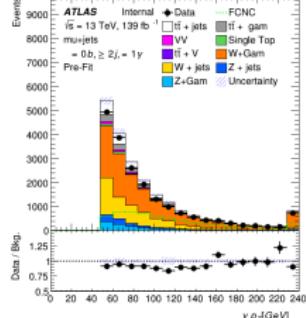

Deviations not unexpected, all SFs optimized for SR

# Validation Regions: $W + \text{jets} + \gamma$

## Electron Channel

## Validation Regions: $t\bar{t} + \text{jets} + \gamma$

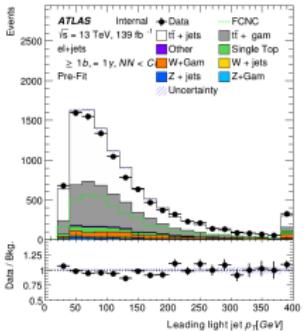

## ► $\gamma p_T$

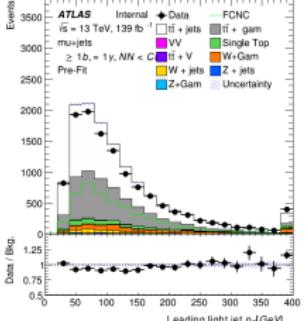

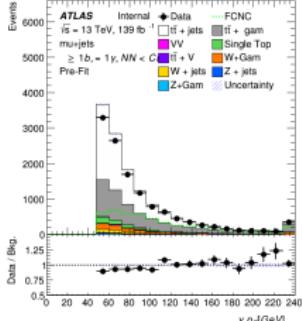

## ► Lead Jet $p_T$

## ► $m_{Wb}$

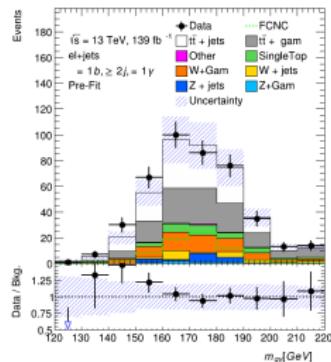

Muon Channel

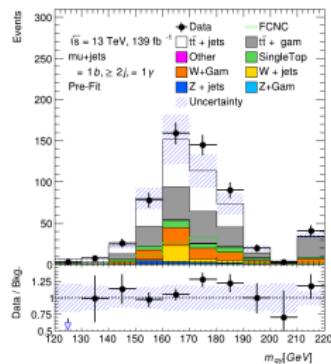

# Pre-fit Signal Region Plots

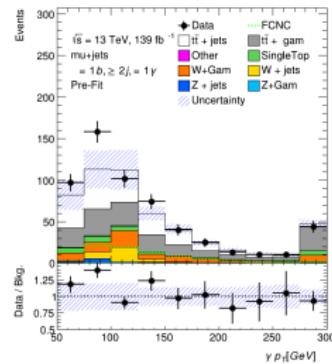

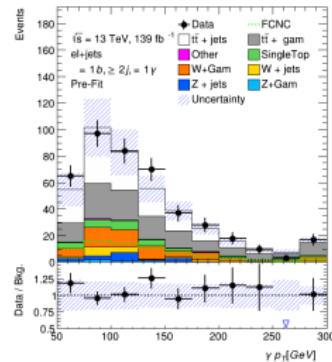

Electron channel

Muon channel

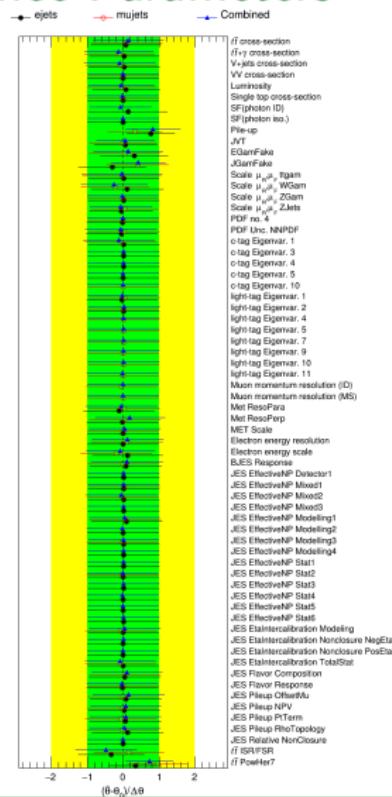

$\gamma p_T$

# Systematic Uncertainties - Nuisance Parameters

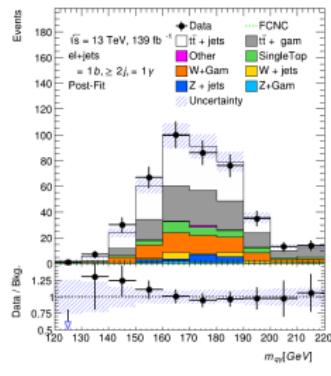

- ▶ Most systematics do not effect fit
- ▶ Largest pulls from Photon and Jet related variables
- ▶ ISR/FSR Variation
- ▶  $j \rightarrow \gamma$  fake rate
- ▶ Changing MC generator
- ▶ Each of these between 1.5-2.5% effect relative to nominal uncertainty

Statistically dominated limit

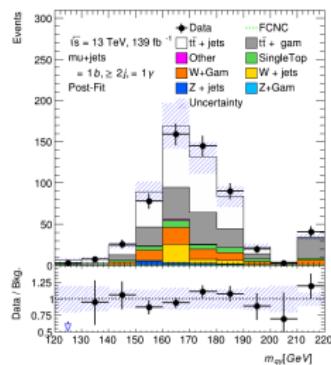

# Post-fit Signal Region Plots

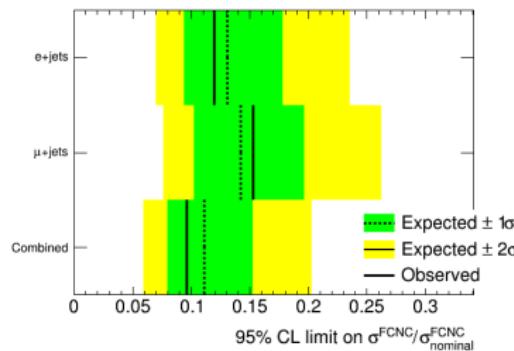

Electron channel

Muon channel

# Result - Limit on $\text{BR}(t \rightarrow q\gamma)$

Channel	Obs. Limit	Exp. Limit
e+jets	$1.19 \times 10^{-4}$	$1.31^{(+0.47)}_{(-0.36)} \times 10^{-4}$
$\mu + \text{jets}$	$1.53 \times 10^{-4}$	$1.42^{(+0.51)}_{(-0.39)} \times 10^{-4}$
Combined	$0.96 \times 10^{-4}$	$1.10^{(+0.43)}_{(-0.30)} \times 10^{-4}$

# Conclusions

- ▶ Limits have been set on the process  $t \rightarrow q\gamma$ , the best current limit on  $t \rightarrow c\gamma$
- ▶ Neural network implementation improved result by up to 30% compared to stats only improvement from 8 TeV result
- ▶ Continuing to prod the Standard Model from all angles is important in searching for new physics

# A Couple BSM Diagrams

- R-parity-violating supersymmetric models  
[arXiv:hep-ph/9705341]
- Top-color-assisted technicolor models  
[arXiv:hep-ph/0303122]

## Jets/AntiKT

$$d_{ij} = \min\left(\frac{1}{p_{ti}^2}, \frac{1}{p_{tj}^2}\right) \frac{\Delta_{ij}^2}{R^2}$$

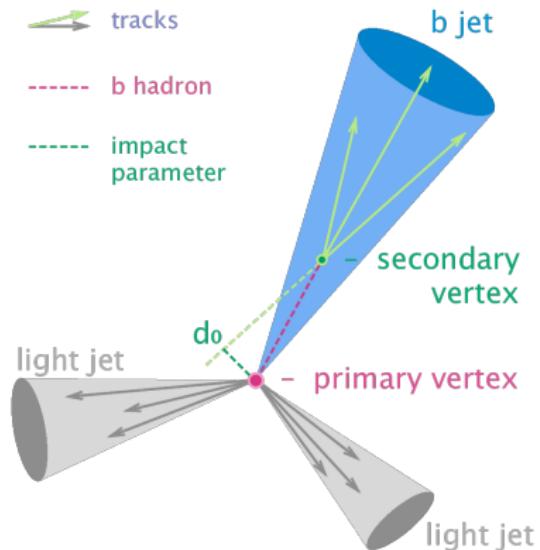

$$d_{iB} = \frac{1}{p_{ti}^2}$$

$$\Delta_{ij}^2 = (\eta_i - \eta_j)^2 + (\phi_i - \phi_j)^2$$

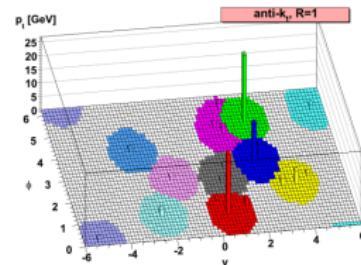

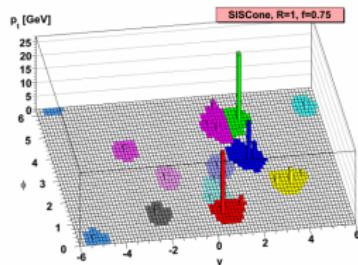

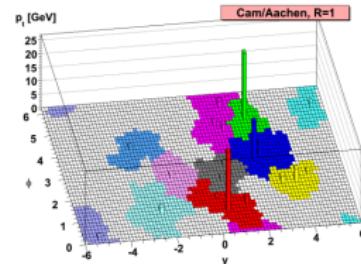

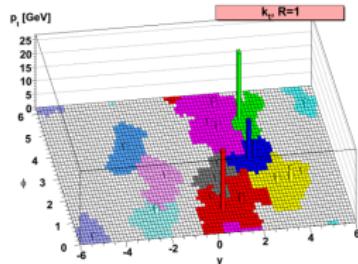

- ▶ Find minimum of entire set of  $\{d_{ij}, d_{iB}\}$
- ▶ If  $d_{ij}$  is the minimum particles i,j are combined into one particle and removed from the list of particles
- ▶ If  $d_{iB}$  is the minimum i is labelled as a final jet and removed from the list of particles
- ▶ Repeat until all particles are part of a jet with distance between jet axes  $\Delta_{ij}$  is greater than R

# B-tagging

- ▶ B Hadrons travel a measurable distance before decay
- ▶ Tracks originate from outside of interaction point (Secondary Vertex)
- ▶ Backtracking tracks in displaced vertex gives an impact parameter
- ▶ Decay chain MVA attempts to reconstruct decay of the jet
- ▶ Outputs of these algorithms used in a BDT to determine if a Jet is from a b-quark

# Jet Algorithms

- ▶ IR Safety: Adding soft emission particle does not change final jet configuration
- ▶ Collinear Safety: Splitting a jet into 2 collinear jets yields the same result, jet size does not matter

# Jet Algorithms

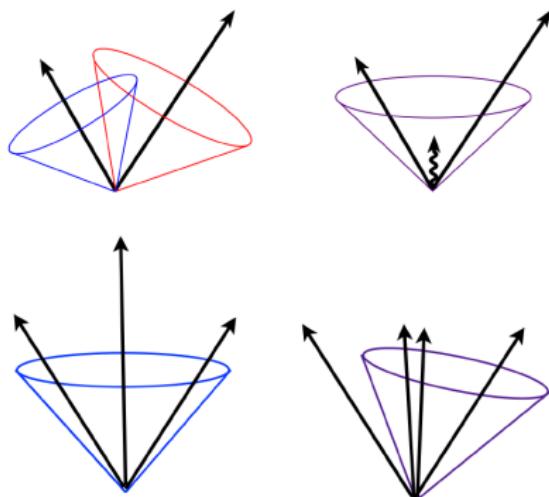

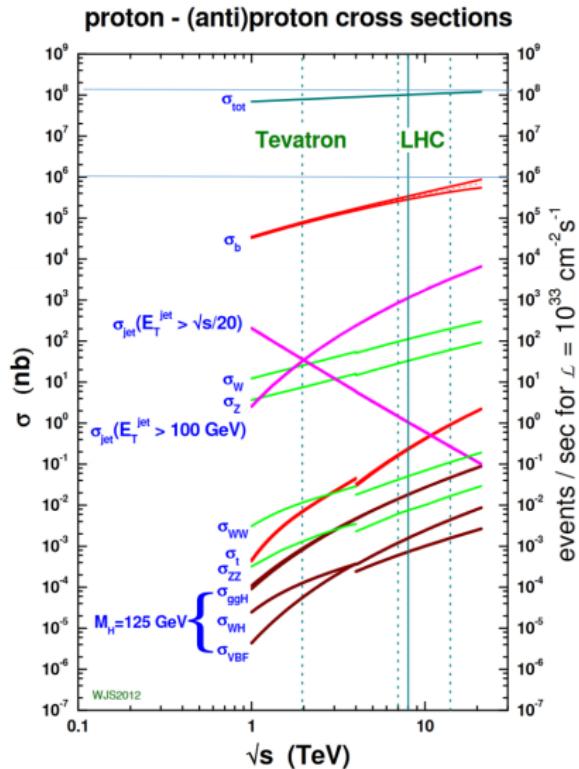

FIGURE 4.4. Illustration of the infrared sensitivity of a cursory designed jet algorithm (top). Illustration of the product of a collinear unsafe jet algorithm. A collinear splitting changes the number of jets (bottom). [52].

## mu+jets Channel Example

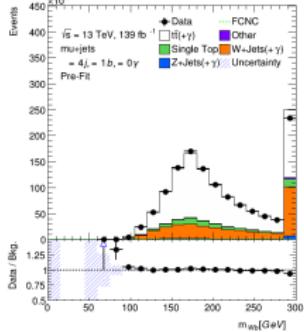

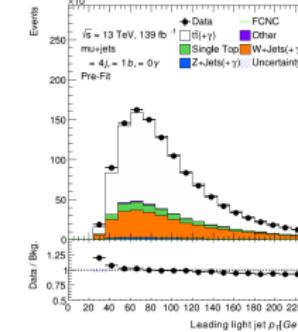

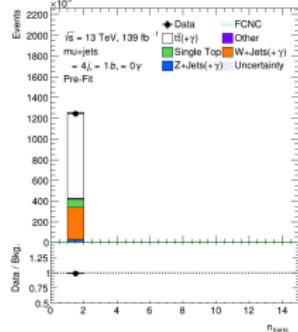

$$\mathcal{L}_{tq\gamma}^{eff} = -e\bar{c}\frac{i\sigma^{\mu\nu}q_\nu}{m_t}(\lambda_{ct}^L P_L + \lambda_{ct}^R P_R)tA_\mu + H.c.$$

# 0 Photon Regions: VR before/after SF, muon channel

Before SF

After SF

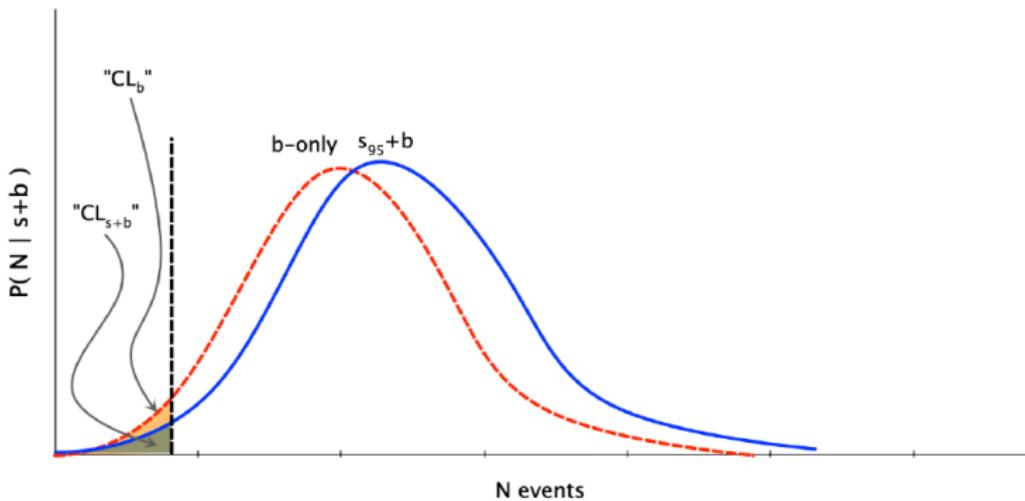

To address the sensitivity problem, CLs was introduced

<http://inspirehep.net/record/599622>

- common (misused) nomenclature:  $CL_s = CL_{s+b}/CL_b$
- idea: only exclude if  $CL_s < 5\%$  (if  $CL_b$  is small,  $CL_s$  gets bigger)

$CL_s$  is known to be “conservative” (over-cover): expected limit covers with 97.5%

- Note:  $CL_s$  is NOT a probability

Cranmer
